1. Introduction

This document is intended to guide you when learning how to define links over the members of a dimension or level. We assume that you have already reviewed the “Introducing STPivot” and “STPivot Installation Guide” documents, successfully deploying STPivot in your Pentaho BI Server of choice; you are also familiar with action sequence definitions and feel yourself ready to try this advanced feature. Previous understanding on how `<jp:clickable>` tag functions is also desirable.

We'll be using the action sequence “Clickables Sample” as shown in the following picture.

2. About Clickables in JPivot

JPivot defines a “clickable” tag that makes all members of a dimension or level clickable (i.e. generates an anchor), where the generated URL contains the unique name of the member.

This tag must be nested either inside a table tag or inside a query tag. Inside the table tag the clickable is available for all queries, inside the query tag its only available for that query. Borrowed from JPivot's documentation ([link](#)), following table lists all available attributes:

Attribute	Description
urlPattern	The pattern to construct the url. If sessionParam attribute is NOT present, then "{0}" will be replaced with the unique name of the member. If urlPattern starts with "/" its relative to the application context, otherwise its absolute. Do not use in conjunction with session parameters because the browser back button does not work as expected. Use “page” attribute instead.
page	Name of the target page, must start with "/". If not set the current page is re-displayed.
uniqueName	Unique name of a dimension, hierarchy or level, whose members will be clickable . It is required always.
menuLabel	If there are multiple clickables specified, they will be displayed in a popup menu, this text will be the label for the menu entry
sessionParam	Name of the parameter, that will be placed into the com.tonbeller.jpivot.param.SessionParamPool
propertyName	If present, the value of that member property will be taken for the com.tonbeller.jpivot.param.Parameter sqlValue property.
propertyPrefix	If present, multiple SessionParam will be created, one for each member property whose name starts with propertyPrefix. The name of the SessionParam will be the name of the reminder of the member properties name after the prefix. If present, the attributes sessionParam and propertyName are not allowed.
providerClass	If present, an instance of this class will extract the SessionParam instances from the member. The class must implement com.tonbeller.jpivot.table.navi.ClickableMember.ParameterProvider. The attributes sessionParam, propertyName, propertyPrefix are not allowed in this case.

For example:

```
<jp:table ...>
...
<jp:clickable urlPattern="/otherpage.jsp?param={0}" uniqueName="[Customers]"/>
<jp:clickable page="/yetotherpage.jsp" uniqueName="[Products].[Category]" sessionParam="Category"/>
...
</jp:table>
```

The behavior depends on the sessionParam attribute. If its present, then the parameter value will be written into the com.tonbeller.jpivot.param.SessionParamPool before the new page is shown. If its not present, the parameter will be coded into the hyperlink and must be treated in some way by the receiving page.

The problem with classic Pivot viewer is that you must hardcode a new viewer, based on classic, to indicate what dimensions and/or levels will be clickable. That's why STPivot uses an incipient mechanism to parameterize this feature in conjunction with the action sequence.

STPivot looks for a parameter containing the list of clickables tag that must be included into the viewer. Then they are placed into a "table" tag, so remains available for further queries. In the next topic you'll see the action sequence definition behind the sample solution.

3. Action Sequence Definition

You'll find two files in the solution folder (stpivot-demos) containing the necessary code for this sample. First of them (demo_clickables.analysisview.properties) is used only for internationalization reasons, and don't need an explanation. The entire action sequence definition is in file "demo_clickables.analysisview.xaction", pasted here for further analysis.

```
1. <?xml version="1.0" encoding="UTF-8"?>
2. <action-sequence>
3.
4.     <name>demo_clickables.analysisview.xaction</name>
5.     <title>%title</title>
6.     <version>1</version>
7.     <logging-level>ERROR</logging-level>
8.     <documentation>
9.         <author></author>
10.        <help/>
11.        <result-type>report</result-type>
12.        <description>%description</description>
13.        <icon></icon>
14.    </documentation>
15.
16.    <inputs>
17.        <mode type="string">
18.            <default-value/>
19.            <sources>
20.                <request>mode</request>
21.            </sources>
22.        </mode>
23.        <!--
24.        In order to define clickable members, stpivot looks for an input param named "clickables".
25.        It is formed by the attributes of <jp:clickable> tags, delimited by semi-colons (";").
26.
27.        Current PivotViewComponent in Pentaho doesn't allow such param in its definition.
28.        That's why we have to define it as input parameter with the default value
29.        we want to send, and then as output param from xaction.
30.        -->
31.        <!-- BEGIN code to enable clickables in stpivot -->
32.        <clickables type="string">

130.    ]]></query>
131.  </component-definition>
132. </action-definition>
133.
134. </actions>
135.
136. </action-sequence>

```

You'll find this action sequence and the one used in First Steps tutorial very similar, differing only in the input and output sections.

If STPivot found a parameter named “clickables”, it is assumed that contains a semicolon separated list of clickable tags (all the attributes except for container tag). No line breaks are allowed for the moment, other wise you'll receive unexpected results. Since the PivotViewComponent provided by Pentaho does not allows you to pass this parameter to STPivot, we are setting them as input parameters; until we develop a new STPivotViewComponent that fix this and other similar issues (by including this parameters in the component-definition section).

You can try now defining your own Clickable members, and give us your feedback so we can fix possible error and/or enhance current solution.
